# Morbidity and Mortality

Weekly Report

## PUBLIC HEALTH SERVICE U.S. DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE

Prepared by the

COMMUNICABLE DISEASE CENTER

MElrose 4-5131

For release June 16, 1961

Atlanta 22, Georgia

Vol. 10, No. 23

## Provisional Information on Selected Notifiable Diseases in the United States and on Deaths in Selected Cities for Week Ended June 10, 1961

Poliomyelitis - Reported cases of poliomyelitis continue at a remarkably low level. Notification of 10 cases, 5 paralytic, was received this week from 7 different States. This week's cases bring the total in 1961 through June 10 to 194 cases, 126 paralytic. The number of paralytic cases reported thus far is just over half the number reported during this same period in 1958, the lowest previous year in over a decade.

Polio (Cumulated Weekly) Through the 23rd Week for the Past 5 Years

	1961	1960	1959	1958	1957
Paralytic	126	253	458	234	497
Total	194	350	652	454	1,048

The occurrence of four cases of paralytic poliomyelitis and two cases of aseptic meningitis in Atlanta represent the only significant concentration of cases yet noted. Five of the six patients are Negro children under five years of age from a localized area in south central Atlanta. From one of the paralytic cases a type III poliovirus has been isolated. Surveys of young children in the immediate neighborhood done in early May as part of a vaccine study revealed carrier rates of type III poliovirus approximating 15 percent. (See Epidemiological Reports)

Thus far in the United States in 1961, specific poliovirus isolates have been identified and reported to the Poliomyelitis Surveillance Unit from 16 cases. Eight of

Figures for current week exclude missing reports from Hawaii

these have been Type I; eight have been Type III. The frequency of Type III isolations is somewhat higher than might be expected although the numbers are yet quite small. A preliminary analysis of the data on poliovirus isolates for 1960 is included under Epidemiological Reports.

### EPIDEMIOLOGICAL REPORTS

## Poliovirus Isolations - 1960, 1961 (Preliminary)

Reports of attempted virus isolations on specimens from 1,530 poliomyelitis cases with onset during the year 1960 were received by the Poliomyelitis Surveillance Unit through March 1, 1961. This represents 46 percent of the total cases submitted to Polio Surveillance Unit.

Poliovirus was isolated from 1,054 cases (69 percent) of the 1,530 specimens studied. Specimens from cases with residual paralysis revealed 76.5 percent polio isolates compared to 60.8 percent in paralytic cases without residual paralysis and to 49.2 percent of cases recorded as nonparalytic poliomyelitis-aseptic meningitis.

Poliomyelitis in 1960 was again predominantly due to type I virus. Of those with virus type specified, 772 (73.7%) were type I and 274 (26.1%) were type III (10% of cases were due to type III in 1959). Type II was isolated in only two cases. The geographic breakdown of poliovirus isolations is shown in the following table by State. A type III outbreak was experienced in Baltimore, Maryland with other concentrations noted in western Maryland, Pennsylvania and New York State.

Thus far in 1961, 11 States have recorded poliovirus isolations from cases of poliomyelitis reported on polio surveillance forms. Idaho, Indiana, Louisiana, New Jersey, Ohio, and Hawaii (2) have noted type I isolates. Type III has been reported from Georgia, Pennsylvania, Utah and three different locations in Washington. Minnesota and Oregon have reported both type I and type III poliovirus from current cases.

## Poliomyelitis - Atlanta, Georgia

Four cases of paralytic poliomyelitis and two cases of aseptic meningitis, etiology undetermined, have been reported from Atlanta.

Age	Sex	Race	Onset	Paralytic Status	Vaccine doses

				In the second second								

The chart shows the number of deaths reported for 117 major cities of the United States by week for the current year, a 5-week moving average of these figures plotted at the central week, and an adjusted average for comparison. For each region the adjusted average was computed as follows: From the total deaths reported each week for the years 1956-1960, 3 central figures were selected by eliminating the highest and lowest figure reported for that week. A 5-week moving average of the arithmetic mean of the 3 central figures was then computed with adjustment to allow for population growth in each region. The average value of the regional increases was 2 percent which was incorporated in the adjusted average shown in the chart.

Table 4 shows the number of death certificates re-

ceived during the week indicated for deaths that occurred in selected cities. Figures compiled in this way, by week of receipt, usually approximate closely the number of deaths occurring during the week. However, differences are to be expected because of variations in the interval between death and receipt of the certificate and because of incomplete reporting due to holidays or vacations. If a report is not received from a city in time to be included in the total for the current week, an estimate is used.

The number of deaths in cities of the same size may also differ because of variations in the age, race, and sex composition of the populations and because some cities are hospital centers serving the surrounding areas. Changes from year to year in the number of deaths may be due in part to population increases or decreases.

Atlanta. The first case has been confirmed by serology as due to Type III poliomyelitis. From the third case, a Type III poliovirus has been isolated from a stool specimen. Other laboratory studies are in process.

It is pertinent to note, that in March, scattered isolates of Type III poliovirus were first isolated from stool specimens taken from young children. In early May, preliminary results show that 15 percent of stool specimens taken from young children in a housing project in the center of this area contained Type III poliovirus. (Reported by Dr. W. J. Murphy, Georgia State Department of Health. Studies jointly conducted by the Fulton County Department of Health and the Enterovirus Unit, Communicable Disease Center.)

## Hepatitis - Menominee Indian Reservation, Wisconsin

Beginning in October 1960, cases of hepatitis commenced to appear among Indian children in the Menominee Reservation, a reservation served by municipal water and sewerage and with a population of 3,200. In all, 28 cases were reported, 22 of these being among children aged 5 to 14, one a 33-year-old adult and the remainder, preschool children. The outbreak appeared to be largely school centered. Because of a continual build-up in cases, a mass gamma globulin prophylaxis program was carried out between February 7 and 9 for children and adults in the schools. Six hundred persons were given gamma globulin using a dosage schedule of approximately .01 cc per pound.

Two cases only occurred following this program. One was in a seven year old girl who developed hepatitis on February 27 and the second, a four year old boy who had the onset of illness on March 6. Both cases represented secondary cases occurring respectively two and one months following primary cases in their households. Neither child had received gamma globulin.

(Reported by Dr. Joseph Preizler, State of Wisconsin Board of Health. Investigated by Dr. George Shinners, District Medical Officer, Green Bay, and Mrs. Elaine W. Neta, Public Health Nurse, Menominee Reservation.)

#### QUARANTINE MEASURES

### New Iraqi Quarantine Regulations for Entrance

All travelers arriving in Iraq from India by sea or air must possess an International Certificate of Cholera vaccination. There are two doses required six days apart, the first dose no more than six months prior to arrival, the second dose no less than six days prior to arrival. Travelers not complying will be placed in Iraqi quarantine for five days. All travelers should be cautioned to comply.

#### SOURCE AND NATURE OF MORBIDITY DATA

These provisional data are based on reports to the Public Health Service from the health departments of each State and Puerto Rico. They give the total number of cases of certain communicable diseases reported during the week usually ended the preceding Saturday. Total figures for the United States and the Pacific Division include data for the States of Alaska and Hawaii. Cases of anthrax, botulism, and rabies in man are not shown in table 2, but a footnote to table 1 shows the States reporting these diseases. When diseases of rare occurrence are reported by a State (cholera, dengue, plague, louse-borne relapsing fever, smallpox, louse-borne epidemic typhus, and yellow fever) this is noted below table 1.

PUBLIC HEALTH SERVICE Communicable Disease Center Atlanta 22, Georgia
